

The *OS* Litepaper

bunnyOS: The OS for Humans × Agents On-Chain

bunnyOS Foundation • Adam Ihsan • Joe Kawai
2026

Abstract

For the entire history of crypto, there has been one kind of user: the human. With the emergence of AI agents as autonomous on-chain participants, a second kind of user now exists. bunnyOS is the first protocol designed from the ground up for both. It provides a shared execution environment where humans and agents collaborate on-chain, each contributing what they do best. Humans provide intent and judgment. Agents provide speed, scale, and precision. The bunny ecosystem — comprising bunnyOS, bunnyEX, bunnies, and bunnyDS — is the infrastructure for the action economy: a world where value accrues not to opinions, but to verified on-chain execution. *OS* is the native token that coordinates every participant across this ecosystem.

THESIS

Two Kinds of Users

For the entire history of crypto, there has been one kind of user: the human. Humans created wallets. Humans signed transactions. Humans navigated protocols, evaluated opportunities, and pressed the button. Yes, we built tools along the way — scripts that automated repetitive

tasks, bots that executed predefined rules, smart contracts that enforced logic without human intervention. But these were tools. They had no intent of their own. They did what they were told, nothing more.

Now we have a second kind of user: the agent. An agent is not a tool. It reasons. It plans. It adapts. It holds a wallet, evaluates opportunities, and executes transactions with genuine intent — not because a rule told it to, but because it determined that was the right action given the context. Agents and humans are both users of the same on-chain environment, but they are fundamentally different. They think differently, act differently, and need different things from the infrastructure around them.

A World Where We Collaborate

bunnyOS imagines a world where humans and agents do not operate in parallel, but together. Not humans using agents as tools. Not agents replacing humans. A shared environment where both contribute what they do best. The agent plans — it scans markets, identifies opportunities, maps out the steps required, and surfaces the best available action. The human reasons — they evaluate the recommendation, apply their own judgment and context, and decide whether to execute.

This division is not a limitation. It is the optimal design. Agents are faster, more consistent, and more data-aware than any human. Humans are more contextual, more accountable, and better at reasoning about things that cannot be fully quantified. Together, they are more capable than either is alone. bunnyOS is the terminal where that collaboration happens.

Good Actions Grow Capital

The reason this matters is simple: good actions lead to growth in capital. Bad actions destroy it. For most of crypto's history, the gap between knowing what to do and actually doing it on-chain was where the vast majority of retail capital stalled — not because users lacked information, but because the infrastructure to act on it did not exist. Influencers shared opinions. Alpha groups distributed signals. Copy-trading platforms mirrored wallets blindly. None of it reliably translated knowledge into good execution.

Everything in the bunny ecosystem is built around facilitating good actions. Not opinions. Not signals. Not content. Actions, verified on-chain, with track records that prove whether they worked. When agents help plan and humans reason and execute, the quality of on-chain action improves. Better actions attract more capital. More capital attracts better bunnies. Better bunnies produce better actions. That is the flywheel bunnyOS is designed to spin.

The First Draft Already Exists

The market has been signaling this transition for years, through two products that defined the edges of the problem. Copy-trading made execution accessible to anyone — follow a wallet, mirror the trades, skip the research — but it was blind. There was no context for why a trade was made, no way to verify a track record before committing capital, and no intelligence behind the action. Managed services went the other direction: professional operators, institutional-grade strategy, real execution quality, but entirely gated. High minimums, no transparency, built for capital that retail users simply do not have.

Between these two poles, the retail user has always been stuck. Too much friction to act independently. Too blind to copy safely. Too small to be managed professionally.

bunnyOS is what has never existed between them. A human × agent terminal where agents plan and humans execute, built on Base, accessible to any retail user. Copy-trading without the blindness. Managed services without the gate.

THE ARCHITECTURE OF EXECUTION

The bunny ecosystem is best understood from the user’s perspective outward: the interface they touch, the marketplace they browse, the intelligence providers they subscribe to, and the backbone that powers it all.

bunnyOS: The Consumer Terminal

Every user enters the ecosystem through bunnyOS. It is a free, open-source terminal that abstracts away the complexity of the blockchain. Instead of navigating wallets, bridges, and fragmented decentralized applications, users interact through natural language:

“Find me the best stablecoin yield.” “Bridge my assets to Base.” “Execute the portfolio rebalance from my DeFi bunny.”

The AI interprets the request, prepares the necessary transactions, and presents them for single-click approval. Execution remains entirely under the user’s control. The complexity is eliminated, not the agency.

bunnyEX: The Marketplace for Action

Inside bunnyOS, users discover and subscribe to bunnies through bunnyEX — the marketplace where the action economy becomes an economy, where bunnies built by humans, agents, or any combination of the two are published, discovered, and subscribed to.

Anyone can launch a bunny and list it on bunnyEX. A bunny is a product: a packaged source of executable actions that its creator offers to bunnyOS users as a service. The creator can be an individual, a team, an AI agent, an automated algorithm, a robot, or any hybrid. Access follows a progressive model: early access is governed by keys, creating social alignment and allowing the best strategies to attract early capital; as track records accumulate, access transitions to subscriptions and performance fees, ensuring creators are rewarded for results rather than hype.

On bunnyEX, humans and agents compete on the same terms. The market does not care whether a strategy was produced by a human analyst or an autonomous agent. It cares whether it worked.

bunnies: Suppliers of Action

A bunny is the foundational unit of the action economy. It is a product and a service — a packaged source of executable on-chain actions that anyone can create and offer to bunnyOS users. The creator builds the intelligence behind the bunny; the bunny is the product they bring to market; bunnyOS users are the customers.

Anyone can launch a bunny: a solo trader, a research team, an AI agent, an automated algorithm, a robot, or any combination of humans and agents. bunnies do not publish opinions. They supply **actions**. A DeFi yield strategy, an airdrop farming route, a portfolio rebalancing sequence — whatever the domain, a bunny’s sole output is executable intelligence delivered directly to its subscribers inside bunnyOS. The same marketplace accommodates a

solo human analyst and a fully autonomous AI agent without distinction. The market decides which produces better results. The infrastructure does not pick sides.

bunnyDS: The Intelligence Backbone

Underpinning every bunny is bunnyDS, the data and inference layer that powers the entire ecosystem. Rather than forcing developers and creators to manage multiple APIs and infrastructure providers, bunnyDS acts as an intelligent aggregator: it routes inference requests across leading AI models, optimizing for cost and speed, and provides standardized access to blockchain data, wallet histories, and DeFi protocol states.

bunnyDS ensures that every bunny, whether built by a human or an agent, has the context required to generate accurate, timely actions. As the ecosystem scales, bunnyDS will expand into a marketplace for specialized inference and on-chain data, allowing developers to monetize their models and data streams directly to the network.

THE ROLE OF *OS*

The action economy requires an economic engine that coordinates every participant: human creators, AI agents, data providers, and retail users. That engine is *OS*.

OS is the native token of the action economy. Its role is structural, not speculative, and it operates at every layer of the ecosystem. **Access:** *OS* is the currency through which users access bunnies on bunnyEX, purchasing keys for early-stage strategies, paying subscriptions for established ones, and settling performance fees when execution produces results. **Infrastructure:** bunnies use *OS* to compensate the data providers and inference nodes on bunnyDS; every AI inference call, every blockchain data query, every third-party API request that powers a bunny's intelligence is settled in *OS*. **Incentives:** *OS* rewards the creators whose bunnies produce the best results, aligning the interests of every intelligence provider — human or agent — directly with the users who rely on them.

How *OS* Is Removed From Circulation

Bonding Curves on bunnyEX. When a bunny launches on bunnyEX, *OS* is locked into a bonding curve that governs the pricing of its keys. As more users purchase keys, the price rises along the curve and more *OS* is locked into the pool. The stronger the bunny, the more *OS* is locked.

Protocol Fees. A portion of every subscription payment, performance fee, and infrastructure settlement on bunnyDS is directed to the protocol and permanently removed from circulation.

Staking for Compute, Data, and Governance. *OS* holders can stake their tokens to access compute resources and data feeds on bunnyDS, securing preferential routing, priority inference, and premium data streams. Staked *OS* also entitles holders to participate in governance and earn a share of protocol fees. In each case, staked *OS* is removed from circulating supply for the duration of the lock.

The value of *OS* is a direct function of execution velocity. As more retail users rely on bunnyOS to automate their on-chain activity, demand for high-quality bunnies rises. As more bunnies launch and attract capital, more *OS* is locked into bonding curves. As execution improves, more users enter the ecosystem, driving more fees and more removal. Each cycle compounds the supply pressure while expanding the demand.

The token does not need to be believed in. It needs to be used.

THE ROAD AHEAD

Crypto moves in quarters, not years. The action economy does not arrive all at once. It is built in layers, each one making the next possible.

Q3 2026 — Onboard bunnies, Track Actions. The first priority is supply: onboarding the initial cohort of bunnies across DeFi, trading, airdrop, and governance strategies, and building the infrastructure to track and display their action history publicly. Before a retail user subscribes to a bunny, they need to see a verifiable record of what that bunny has published and what it has produced. Track records, not promises.

Q4 2026 — Enable Autonomous Execution. bunnyOS moves from assisted execution, where the AI prepares a transaction for user approval, to autonomous execution, where users can authorize a bunny to act on their behalf within defined parameters. This is the moment the pipeline closes. The human sets the intent. The agent handles the rest.

Q1 2027 — Grow the Marketplace. More bunnies, more strategies, more track records. The keys model opens up to subscriptions and performance fees, transitioning bunnyEX into a fully functioning marketplace where humans and agents compete on results.

Q2 2027 and Beyond — Products Around the Action Economy. bunnyDS expands from an aggregator into a marketplace for specialized inference and on-chain data. New products are built around the action economy primitive: portfolio automation, strategy vaults, agent-to-agent coordination, and more. *OS* deepens as the settlement layer across every product in the ecosystem. The goal is a self-sustaining network where bunnies compete on execution quality, users compound returns through automated strategies, and *OS* velocity reflects real economic activity rather than speculation.

THE VISION

The bunny ecosystem is not just building a terminal and a marketplace. It is building the first protocol designed from the ground up around the humans $\times$ agents primitive, and that primitive unlocks an entirely new class of on-chain products that do not yet exist.

Every major infrastructure layer in crypto has eventually spawned products that were unimaginable before it existed. Smart contracts gave us DeFi. NFTs gave us digital ownership. L2s gave us scalable execution. The humans $\times$ agents primitive gives us something new: financial products and experiences that are only possible when human judgment and agent precision operate together.

Human $\times$ Agent ETFs. Index products where the composition and rebalancing logic is co-designed by human strategists and agent execution systems — combining human macro judgment with agent-level precision and speed. Not a passive index. Not a fully automated vault. Something in between that has never existed.

Collaborative NFTs and Reputation Primitives. On-chain identity and reputation systems that reflect the combined track record of a human creator and the agents they deploy — a new kind of asset representing not just ownership, but verified collaborative execution history.

Human × Agent Coordination Mechanisms. New governance and coordination structures where humans set the parameters and intent, and agents execute and monitor in real time. DAOs that actually work because the execution layer is automated, but the judgment layer remains human.

These are not incremental improvements to existing products. They are a new category, made possible only by the infrastructure bunnyOS is building. The bunny ecosystem is the first protocol to stake a claim on this category.

The products that will define the next era of crypto have not been built yet. They will be built here.

CONCLUSION

The attention economy rewarded whoever spoke loudest. The action economy rewards whoever executes best. For the entire history of crypto, there was one kind of user. Now there are two. The infrastructure needs to be built for both, and the products that emerge from that infrastructure will be unlike anything the market has seen.

The bunny ecosystem is that infrastructure. The first protocol built around the humans × agents primitive, on-chain.

OS is the protocol for action.
